- I am Dhinesh KS. A self motivated and dynamic engineering graduate specialized in Mechanical from Sastra University.
- I would love to work in a faced learning environment to update my knowledge base with latest trends and to share it with the people having similar thirst.

## Deforestation Content

IMAGE

Forests are a rich resource of our planet, Earth. Pristine forests provide benefits to the ecosystem that a re-created forest cannot create. Therefore it is important to protect our forests. Deforestation refers to loss of forest cover due to clearing of trees and vegetation in the forest. Deforestation leads to ecological and environmental disturbance and imbalance. Forests are habitats that play host to many wildlife species. A wide variety of animals, birds, reptiles and insects inhabit forests. The wildlife species that live in forests depend on the forests for their food, and complete their life cycle in the forest. When trees are cut, all the inhabitant creatures suffer. Man too depends on forest products for his food. Communities that live near forests depend on the forests for their livelihood. These communities have been living near the forests over several generations, and are keen protectors of the forests. They adopt traditional environment-friendly practices. Deforestation therefore affects local communities. Forests are important in maintaining the hydrological cycle in an ecosystem. When forests are left undisturbed the rainfall patterns are normal. The water table is also high enough to be available for man's use for his various requirements to maintain his life and livelihood. All life forms need water. Not only do marine species need water bodies, all terrestrial creatures too depend on water for their life. Loss of forest cover leads to disturbances in the hydrological cycle and climate patterns too. Deforestation therefore leads to long term ecological disequilibrium and environmental hazards.....
